(54) Title: FLUID EXTRACTOR

(57) Abstract

A mucus extractor comprises a symmetric vessel (1) with an inlet connection (14) for a mucus tube (16) and an outlet connection (15) for a suction tube (17). The diaphragm (12) peripheral is captive at the plane of symmetry. The diaphragm (12) is separating a space (22) to be collapsed by suction from a receiving space (23) into which mucus is drawn by the suction. The effect of the diaphragm (12) is to prevent mucus from entering the suction tube (17) which could be both unpleasant and dangerous.

Fluid Extractor

Field of the Invention

The present invention relates to a fluid extractor, particularly though not exclusively a mucus extractor.

Background of the Invention

A conventional mucus extractor comprises a small jar, a lid to the jar having two connections and a pair of tubes one connected to one connection and having at its free end a mouthpiece, the other connected to the other connection and having at its free end a nozzle for insertion into a new born baby's nostrils and/or mouth. In use, the nozzled tube is inserted into the baby's nose for instance and a midwife sucks on the mouthpiece to draw mucus from the baby's air passages to assist its initial breathing. Because a midwife can be extremely busy at this stage in the baby's birth, she may omit to notice the complete filling of the jar with mucus. Then she may suck up mucus into her own mouth. Not only can this be extremely unpleasant; but also it is potentially dangerous as regards infectious diseases.

British patent specification No: 1,273,742 describes a mucus extractor suffering from this defect. It has an inlet for mucus to a container which is oppositely directed to a suction air outlet from he container. However if the container fills to the level of the air outlet, mucus will be sucked up.

British patent application specification No: 2,017,497A describes a mucus extractor having an inflatable inner bag separated from an outer chamber from which suction air is withdrawn.

The Invention

30

The object of the invention is to provide an improved mucus extractor.

According to the invention there is provided an extractor comprising:-

5

10

25

a vessel for receiving extracted fluid, the vessel being closed in use except for a fluid inlet connection for allowing fluid into the vessel and an air outlet connection for allowing withdrawal of air from the vessel;

a flexible diaphragm arranged in the vessel to divide a separated space within the vessel from a fluid receiving space, flexibility of the diaphragm allowing increase in volume of the receiving space on concomitant decrease in volume of the separated space with withdrawal of air therefrom;

a fluid inlet tube connected to the inlet connection for conveying fluid into the receiving space; and an air outlet tube connected to the outlet connection for withdrawal of air from the separated space.

It is envisaged that the extractor may have uses other than as a mucus extractor, for instance as a lock preventing ingestion of liquid from a pipette. However, since the extractor has been invented for use as a mucus extractor, it will be described further in this context.

20 For use as a mucus extractor, the air outlet tube is provided with a mouthpiece, and the fluid tube is preferably provided with a nozzle.

In use the nozzle of the mucus tube is inserted into a baby's mouth or nose and mucus is withdrawn by suction on the mouthpiece of air tube. Suction causes deflection of the diaphragm with reduction of the volume of the separated space and increase in volume of the mucus receiving space into which mucus is drawn, since there is no appreciable pressure differential across the diaphragm.

Should a midwife go on sucking after the diaphragm has moved fully to cause the separated space to be minimized and the mucus receiving space to reach a maximum volume, the mucus cannot be sucked up the air tube because the diaphragm provides permanent separation.

35 An additional unexpected advantage is that should the

35

mucus receiving space be full with air and/or mucus and yet further mucus still need to be extracted from the baby, that in the receiver can simply be expelled by tipping the extractor and blowing into the air outlet tube and expelling the mucus via the inlet tube into a suitable receptacle.

Then a further extraction operation can be effected.

Preferably, the flexible diaphragm is adapted to at least partially invert between an initial rest position in which the separated space is at a maximum volume and an ultimate position in which the separated space is drawn down to a minimum volume, the diaphragm having at least one peipheral region at which it undergoes substantial angular deviation between its initial position and its ultimate position. The extractor will be manufactured with the diaphragm in its initial rest position. Should it have become displaced prior to use, blowing into the air outlet tube will restore it to its initial position. Then the air pressure can be released prior to use to leave the diaphragm in its initial position.

Conveniently, the flexible diaphragm has two peripheral 20 regions at which it undergoes the said substantial angular deviation and a central area bounded by one of the said regions, tthe central area being substantially flat in both the maximum and minimum volume conditions of the separated space. The other of the said regions may be adjacent a 25 fixed edge of the flexible diaphragm. Alternatively the diaphragm may have a generally tubular portion extending between a fixed edge and one or both of the said peripheral regions at which it undergoes the said substantial angular deviation, the peripheral regions being arranged around the tubular portion. In this case, the other of the said peripheral regions (where two are provided) is at a peripheral fold in the generally tubular portion of the diaphragm.

In one embodiment, the vessel is symmetric, the

25

diaphragm peripheral being captive at the plane of symmetry. Although the diaphragm may extend at rest in this plane of symmetry, preferably it extends out of the plane to lie close to or in contact with a sidewall of the vessel on its receiving space side, in order to maximise the usable receiving space by causing it to be a minimum prior to use and to allow the diaphragm to cross the plane of symmetry without resilient tendency to return to lie in this plane (which tendency would have to be overcome by suction on the 10 air tube). The vessel is preferably provided with ribbing internally extending from the connections to avoid suction of the membrane across the outlet connection in such a manner as to close it prior to complete evacuation of the space being evacuated.

In another embodiment, the vessel has a removable, sealing lid incorporating the inlet and outlet connections, the fixed edge of the diaphragm is fixed to the removable lid and the diaphragm depends from the lid.

To help understanding of the invention, two specific embodiments thereof will now be described by way of example and with reference to the accompanying drawings in which:

The Drawings

Figure 1 is a cross-sectional side view of a mucus extractor according to the invention on the line I-I in Figure 1;

Figure 2 is a cross-sectional underneath plan view of the mucus extractor of Figure 1 on the line II-II in that figure;

Figure 3 is an enlarged scrap view of a detail of Figure 30 2;

Figures 4, 5 and 6 show diagrammatically use of the mucus extractor of Figure 1;

Figure 7 is a cross-sectional side view of another mucus extractor according to the invention on the line VII-VII in 35 Figure 9;

Figure 8 is a scrap view of a detail of Figure 7; and Figure 9 is a plan view of the mucus extractor of Figure 7.

First Embodiment

Referring first to Figures 1, 2 and 3, the mucus 5 extractor has a vessel 1 which is an assembly on a plane of symmetry 2 of two injection moulded shells 3,4. The shells are of clear plastics material such as acrylic or polystyrene. Each, identical, shell is of trapezoidal shape, being initially open at its base plane. A rim 5,6 is provided extending outwardly at the base plane. In the surface of the rim 5,6, which will mate with the other 6,5 on assembly, there is provided a continuous groove 7,8 extending around the entire rims 5,6. Inwardly of the grooves 7,8 the mating surface of the rims 5,6 is relieved 9,10 to leave a small gap which is occupied by an edge portion 11 of an elastomeric diaphragm 12 of neoprene, polyurethene or natural rubber. At its edge the diaphragm has a bead 13 captive after assembly in the grooves 7,8. On assembly of the diaphragm to one shell, typically 3 into 20 which the diaphragm 12 extends in its free state, and of the other shell 4 to the one, the two shells are welded, as by ultrasound, or adhered together at the rims 5,6, thereby sealing the diaphragm to both shells.

Each shell 3,4 has an integrally moulded connection spout 14,15 to each of which is connected a tube 16,17. With the diaphragm extending towards the shell 3 in its free position, the tube 16 becomes the mucus inlet tube and is provided at its free end with a nozzle 18 in the form of a slight tapering of the tube. The other, air outlet, tube 17 has at its free end a mouthpiece 19. To avoid suction or pressing of the diaphragm against the inner orifice of either spout 14,15 without the diaphragm lying close against the rest of the respective shell 3,4, ribs 20,21 extend on the inner surface of the shells to the opposite ends thereof

thus providing fluid communication from the spouts to the other ends of the shells.

In use, with the diaphragm 12 initially lying close to or against the shell 3, because of the shape of the diaphragm as moulded, the separated space 22 between the diaphragm and the other shell 4 is at a maximum, see Figure This space 22 is separated from the mucus tube 16 by the diaphragm. On insertion of the nozzle 18 into mucus and suction on the air tube 17 via the mouthpiece 19, the volume of the separated space reduces as the diaphragm moves away from the shell 3, see Figure 5. This movement leaves a mucus receiving space 23 between the shell 3 and the diaphragm. Mucus 24 is drawn into this space 23, until the diaphragm lies fully against the shell 4, see Figure 6. 15 This results in substantial angular deviation of adjoining parts of the diaphragm at two peripheral regions 25,26. Region 25 is adjacent the captive edge 11 of the diaphragm. Region 26 is adjacent a central area 27 of the diaphragm which is flat in the rest position of the diaphragm, Figure 20 4, and in the fully inverted position, Figure 6, of the diaphragm. The angular deviation of the diaphragm is approximately 140°.

If insufficient mucus has at this stage been extracted from the baby, the already extracted mucus 24 can be expelled into a suitable receptacle by blowing through mouthpiece 19. A further extraction can then be carried out. At no time can mucus be drawn through the air tube 17.

Second Embodiment

Turning now to Figures 7, 8 and 9, a second mucus

extracor will now be described. It has a vessel 100

comprised of a tub 101 and a screw-top lid 102. The lid has
a mucus inlet connection 103 for a mucus inlet tube 104 and
an air outlet connection 105 for an air outlet tube 106.

Depending from the lid 102 within the tub 101 is a

diaphragm-guiding, circular cylinder 107 and a plurality of

resilient, catch fingers 108. Both lid and the tub are injection moulded of material such as polyethylene. The fingers 108 are arranged circularly around the cylinder 107, outwardly of a circular bead 109 integrally moulded on the inner face of the lid.

A tubular diaphragm 110 is fitted over the guide cylinder 107, with a radially extending rim 111 captive by a ring 112 held by the fingers 108, see in particular Figure The ring 112 has a bead 113 opposite the lid bead 109, so that, when the ring is snapped into position held by the fingers, the diaphragm rim lll is sealingly fixed to the lid. The diaphragm has a tubular portion 114 extending outside the guide cylinder 107 as far as a peripheral S fold Beyond this, the diaphragm extends as a further 15 tubular portion 116 to a central bottom 117, which is substantially flat and closes the tubular portions of the The tubular portions 114, 116 are of substantially the same length. The diaphragm divides the internal space of the vessel 100 into a separated space 122 and a receiving space 123. 20

In use, a nozzle (not shown) on the mucus inlet tube 104 is inserted into a neonate's nostril and suction is applied to a mouthpiece (not shown) on the air outlet tube 106. diaphragm is displaced from its rest position in Figure 7. On progressive displacement, the S fold 115 rolls upwards 25 inside the guide cylinder 107, with the diaphragm locally inverting and deflecting at the S fold through 180°. lower tubular portion 116 and the central bottom 117 of the diaphragm move up towards the lid. The fully displaced, 30 inverted position of the diaphragm is shown in dashed outline 118. In this position the corner 119 between the tubular portion 116 and the central bottom 117 turns To avoid any inside-out with an angular deflection of 180°. possible bowing of the central portion 117 closing the air outlet 105, ribs 120 radiating therefrom on the inner face

of the lid 102 are provided. It will be noted that although the diaphragm deflects from bottom to top of the vessel it is of smaller diameter than the tub, therefore the maximum volume displaced by the diaphragm is less than the total volume available for receiving mucus. Accordingly, at least with one deflection of the diaphragm, air is left above the mucus drawn into the extractor and the mucus cannot syphon back out when the extractor is stood with its flat bottom 121 on a level surface. To render the diaphragm light and thin, it is of blow-, vacuum- or dip-moulded elastomer such as silicone rubber.

Should the mucus be required for analysis, the lid 102 can be replaced by a conventional screw top lid.

The invention is not intended to be restricted to the 15 details of the above described embodiments. For instance, the two shells 3, 4 may have resilient formations such that they clip together on assembly, captivating the diaphragm and sealing it to each of them. Alternatively, where the diaphragm and the shells are all of the same material, for 20 instance polyethylene the diaphragm may be welded or adherred to both shells. The lid 102 may be resiliently or indeed permanently secured onto the tub 101. The diaphragm 110 may be bonded onto the lid 102. The rolling diaphragm may be replaced by other configurations such as a 25 hemispherical diaphragm or a bellows diaphragm.

10

Claims

1. A fluid extractor comprising:-

ultimate position.

- a vessel (1:100) for receiving extracted fluid, the vessel being closed in use except for a fluid inlet connection (14:103) for allowing fluid into the vessel and an air outlet connection (15:105) for allowing withdrawal of air from the vessel;
- a flexible diaphragm (12;110) arranged in the

 vessel to divide a separated space (22,122) within the

 vessel from a fluid receiving space (23;123), flexibility of

 the diaphragm allowing increase in volume of the receiving

 space on concomitant decrease in volume of the separated

 space with withdrawal of air therefrom;
- a fluid inlet tube (16;104) connected to the inlet connection for conveying fluid into the receiving space; and an air outlet tube (17;106) connected to the outlet connection for withdrawal of air from the separated space.
- 2. A fluid extractor as claimed in claim 1, wherein the flexible diaphragm (12;110) is adapted to at least partially invert between an initial rest position in which the separated space is at a maximum volume and an ultimate position in which the separated space is drawn down to a minimum volume, the diaphragm having at least one peripheral region (25,26;115,119) at which it undergoes substantial angular deviation between its initial position and its
- A fluid extractor as claimed in claim 2, wherein the flexible diaphragm (12;110) has two peripheral regions
 (25,26;115,119) at which it undergoes the said substantial angular deviation and a central area (27;117) bounded by one of the said regions, the central area being substantially flat in both the maximum and minimum volume conditions of the separated space (22;122).
- 35 4. A fluid extractor as claimed in claim 3, wherein the

- other (25) of the said regions is adjacent a fixed edge (11) of the flexible diaphragm.
- 5. A fluid extractor as claimed in claim 4, wherein the vessel comprises two substantially identical halves (3,4)
- joined at a medial plane (2) at which the edge (11) of the diaphragm is fixed.
 - 6. A fluid extractor as claimed in claim 3, wherein the diaphragm has a generally tubular portion (114,116) extending between a fixed edge (111) and one or both of the
- said peripheral regions (115,119) at which it undergoes the said substantial angular deviation, the peripheral regions being arranged around the tubular portion.
 - 7. A fluid extractor as claimed in claim 6, wherein the other (115) of the said peripheral regions is at a
- peripheral fold (115) in the generally tubular portion (114,116) of the diaphragm.
 - 8. A fluid extractor as claimed in any one of claims 1 to 4, 6 and 7, wherein the vessel has a removable, sealing 1id (102) incorporating the outlet connection (103), a fixed
- 20 edge (lll) of the diaphragm being fixed to the removable lid and the diaphragm depending from the lid.
 - 9. A fluid extractor as claimed in claim 8, wherein the removable lid (102) incorporates the inlet connection (105).
- 10. A fluid extractor as claimed in either of claims 8 and 9
 as appendant to claim 7, wherein the lid has a depending cylinder (107) extending inside the diaphragm as far as the fold (115) for controlled, rolling movement of the diaphragm.
- 11. A fluid extractor as claimed in any preceding claim,
 30 wherein the extractor has a flat bottom (121) and the inlet
 connection (103) is remote from the flat bottom.
 - 12. A fluid extractor as claimed in any preceding claim, wherein the maximum volume of the separate space (122) is less than the maximum volume of the receiving space (123).
- 35 13. A fluid extractor as claimed in any preceding claim,

including ribs (20,21;120) on the inside of the vessel radiating from the outlet connection (15;105).

- 14. A fluid extractor as claimed in any preceding claim,
 wherein the flexible diaphragm (12;110) is of vacuum-, blowor dip-formed elastomeric material.
 - 15. A fluid extractor as claimed in any preceding claim, wherein the inlet tube (16;104) has a nozzle (18) adapting the extractor for extracting mucus from a nostril of a neonate and the outlet tube (17;106) has a mouthpiece (19)

10 for human suction on the outlet tube.
